## Griffing methods (1956)

1. One set of F1's and reciprocals [ $p^{2}$ genotypes] plus parents
2. One set of F1's, no reciprocals [p(p+1)/2 genotypes] plus parents
3. One set of F 1 's and reciprocals [ $p(p-1)$ genotypes], no parents
4. One set of F1's, no reciprocals [ $p(p-1) / 2$ genotypes] no parents

## Mathematical model for RCB

$x_{i j k l}=\mu+v_{i j}+b_{k}+(b v)_{i j k}+e_{i j k l}$
where $\mu$ is the population mean effect
$v_{i j}$ is the effect for the $i j$ th variety (i.e. genotype)
$b_{k}$ is the $k$ th block effect
$(b v)_{j j k}$ is the interaction between the $i j$ th genotype and the $j$ th block
$e_{i j k l}$ is the environmental effect associated with the $i j k / t h$ individual
In this model, there are $a$ varieties randomized to $b$ blocks with $c$ individual measurements taken in each of the $a b$ plots

## The variety effects in the model $x_{i j k l}=\mu+v_{i j}+b_{k}+(b v)_{i j k}+e_{i j k l}$

are considered in terms of GCA and SCA:

For methods in which reciprocal F1's are included

$$
v_{i j}=g_{i}+g_{j}+s_{i j}+r_{i j}
$$

where $g_{i}$ is the GCA effect of the ith parent,
$s_{i j}$ is the SCA effect for the cross of the $i$ th and $j$ th parents, and $r_{i j}$ is the reciprocal effect involving the $i$ th and $j$ th parents.

For methods in which reciprocal F1's are not included, $r_{i j}$ is zero

$$
v_{i j}=g_{i}+g_{j}+s_{i j}
$$

## Models

I. All effects except error are regarded as 'fixed'
II. All effects except $\mu$ are considered 'random'

In Model 1, inferences are limited to the experimental materials. Useful in comparing combining abilities among the parent lines. Can identify good hybrid combinations.
In Model 2, inferences are not about the individual lines in the sample but rather extend to the population of lines. Useful in estimating genetic components of the population variance.

## Expected Means Square table for RCB

| Source of <br> Variation | Degrees of <br> Freedom | Mean <br> Square | Model I | Model II |
| :--- | :--- | :--- | :--- | :--- |
| Varieties | $\mathrm{a}-1$ | $M_{v}$ | $\sigma_{e}^{2}+b c\left(\frac{1}{a-1} \sum_{v_{i}^{2}}\right)$ | $\sigma_{e}^{2}+c \sigma_{b v}^{2}+b c \sigma_{v}^{2}$ |
| Blocks | $\mathrm{b}-1$ | $M_{b}$ | $\sigma_{e}^{2}+a c\left(\frac{1}{b-1} \sum_{k} b_{k}^{2}\right)$ | $\sigma_{e}^{2}+c \sigma_{b v}^{2}+a c \sigma_{b}^{2}$ |
| Varieties x blocks | $(\mathrm{a}-1)(\mathrm{b}-1)$ | $M_{b v}$ | $\sigma_{e}^{2}+c\left(\frac{1}{(a-1)(b-1)} \sum_{i<} \sum_{j} \sum_{k} b v_{i j k}^{2}\right)$ | $\sigma_{e}^{2}+c \sigma_{b v}^{2}$ |
| Error | $\mathrm{ab}(\mathrm{c}-1)$ | $M_{e}$ | $\sigma_{e}^{2}$ | $\sigma_{e}^{2}$ |

Note that if $c=1$ (i.e. no subsampling), then $M_{b v}$ becomes the error term $M_{e}$

## Expected Means Square table for Method 4

| Source of <br> Variation | Degrees of <br> Freedom | Mean <br> Square | Model I | Model II |
| :--- | :--- | :--- | :--- | :--- |
| GCA | $p-1$ | $M_{g}$ | $\sigma^{2}+(p-2)\left(\frac{1}{p-1}\right) \sum_{i} g_{i}^{2}$ | $\sigma^{2}+\sigma_{s}^{2}+(p-2) \sigma_{g}^{2}$ |
| SCA | $p(p-3) / 2$ | $M_{s}$ | $\sigma^{2}+\left(\frac{2}{p(p-3)}\right) \sum_{i<} \sum_{j} s_{i j}^{2}$ | $\sigma^{2}+\sigma_{s}^{2}$ |
| Error | $m$ | $M_{e}^{\prime}$ | $\sigma^{2}$ | $\sigma^{2}$ |

Note $M_{e}{ }^{\prime}=M e / b c$
with the same number of d.f.'s: $m$
To test for GCA effects: $F_{[(p-1), m]}=M_{g} / M_{e}{ }^{\prime}$

To test for SCA effects: $\quad F_{[p(p-3) / 2, m]}=M_{s} / M_{e}{ }^{\prime}$

## Compute estimates of effects for Method 4

$$
\begin{aligned}
& x_{i j k l}=\mu+v_{i j}+b_{k}+(b v)_{i j k}+e_{i j k l} \\
& v_{i j}=g_{i}+g_{j}+s_{i j}
\end{aligned}
$$

Of particular interest is the estimate of GCA effects for parents, $g_{i}$, and the SCA effects for specific hybrid combinations of parents, $s_{i j}$
$g_{i}=\frac{1}{p(p-2)}\left(p X_{i .}-2 X_{. .}\right) \quad s_{i j}=x_{i j}-\frac{1}{(p-2)}\left(X_{i .}+X_{j .}\right)+\frac{2}{(p-1)(p-2)} X_{.}$
given $\quad X_{i .}=\sum_{j \neq i} x_{i j} \quad$ where $\quad x_{i j}=x_{j i} \quad$ e.g. $X_{2 .}=x_{12}+x_{23}$
And

$$
X_{n}=\sum_{i<j} \sum_{x_{i j}}
$$

## Estimating breeding value (BV)

Once estimated GCA effects for parents, $g_{i}$, are obtained, the expected values of progeny resulting from hybrid combinations of parents can be calculated:

$$
E\left(x_{i j}\right)=\mu+g_{i}+g_{j}
$$

Note that SCA effects are not included. Why? Because nonadditive effects cannot be transmitted to progeny in the case of diploids.
Also note that $E\left(x_{i j}\right)$ is the same as an estimated breeding value (EBV). The predicted performance of the progeny is the average of the breeding values of the parents. Thus, the breeding value of a parent line is twice its GCA:

## $B V=2 G C A$

The SCA effect for specific hybrid combinations of parents, $s_{i j}$, can be calculated as difference between actual and expected performance:

$$
s_{i j}=x_{i j}-E\left(x_{i j}\right)
$$

## Exercise

Data were gathered on potato leaf roll virus (PLRV) resistance from crosses among 7 lines from a native regional population of potato, Solanum tuberosum ssp andigena (Mihovilovich et al.2007). The 7 lines were crossed in a diallel design, Griffing Method 4 (no reciprocals, F1 crosses only) and evaluated under greenhouse conditions using viruliferous aphids as an inoculation source. An RCB design with 3 replications was employed.
The mean percentage of resistance to PLRV infection was scored and data were transformed to arc sen (>80\% resistance equivalent to $>70$ transformed arc sen). Table 1 displays the mean arc sen for percentage PLRV resistance for the F1 crosses among the 7 lines. Table 2 is the ANOVA table from the data analysis.

## TABLE 1. Mean are sen percentage PLRV resistance

| CROSS | L 1 | L 2 | L 3 | L 4 | L 5 | L 6 | L7 | TOTAL |

## Exercise

1. What is $a, b, c, p$ ? Show formulas.
2. What are the formulas for the d.f's? Hint: show how the number of d.f. given were computed.
3. Show how $M_{e}{ }^{\prime}$ was calculated.
4. Was the analysis performed as a Model 1 (fixed) or Model 2 (random)? How do you know? What this appropriate?
5. Based on the ANOVA, what do you conclude about gene action controlling PLRV in potato? Why?
6. Compute the GCA and SCA effects to populate Table 3.
7. If you were to select 3 lines based on their GCA, which lines would you choose?
8. Which F1 cross showed the highest SCA?
9. What is the expected value of progeny resulting from L1 x L7?

## Exercise - ANSWER KEY

1. What is $p, a, b, c$ ? Show formulas.
$p=7 ; a=p(p-1) / 2=7(6) / 2=21 ; b=3 ; c=1$
2. What are the formulas for the d.f.'s? Hint: show how the number of d.f. given were computed.
See ANSWER KEY TABLE 2
3. Show how $M_{e}^{\prime}$ was calculated.
$M_{e}{ }^{\prime}=M_{e} / b c=48.8625 / 3(1)=16.2875$
4. Was the analysis performed as a Model 1 (fixed) or Model 2 (random)? How do you know? What this appropriate?
Model 2 was used; the lines were sampled from a native regional population of potatoes. See EMS terms for GCA and SCA behind F test in ANSWER KEY TABLE 2
5. Based on the ANOVA, what do you conclude about gene action controlling PLRV in potato? Why?
The ANOVA indicates that GCA is highly statistically significant, whereas SCA is not significant. Because GCA reflects mainly additive effects, we can conclude that additive gene action is largely controlling PLRV resistance and non-additive effects (dominance and epistasis) are not involved to any significant extent.

## Exercise - ANSWER KEY (cont)

6. Compute the GCA and SCA effects to populate Table 3. See ANSWER KEY TABLE 3
7. If you were to select 3 lines based on their GCA, which lines would you choose?
By rank: L5, L6, L3 have highest GCA. L5 is outstanding at 31.82
8. Which F1 cross showed the highest SCA? L2 $\times$ L5 with SCA at 9.50
9. What is the expected value of progeny resulting from L1 $x$ L7?
$E\left(x_{17}\right)=\mu+g_{1}+g_{7}=40.38+-3.38+-5.67=31.33$
Also note that
$s_{17}=x_{17}-E\left(x_{17}\right)=39.18-31.33=7.84$
